ABSTRACT
A new hybrid power conditioner for solving the problems of harmonic currents and neutral-line current in three-phase four wire distribution power systems is proposed in this paper. This hybrid power conditioner is configured by a neutral-line current attenuator and a hybrid power filter. The hybrid power filter, configured by a three-phase power converter and a three phase tuned power filter, is utilized to filter the nonzero-sequence harmonic currents in the three-phase four-wire distribution power system. The neutral-line current suppressor is connected between the power capacitors of the three-phase tuned power filter and the neutral line to attenuate the neutral-line current in the three-phase four-wire distribution power system. The proposed hybrid power conditioner can effectively reduce the power rating of passive and active elements. A simulation results is developed to verify the performance of the proposed hybrid power conditioner.

Index Terms—Harmonic, neutral-line current, power converter.

INTRODUCTION
Power conditioner
A power conditioner (also known as a line conditioner or power line conditioner) is a device intended to improve the quality of the power that is delivered to electrical load equipment. While there is no official definition of a power conditioner, the term most often refers to a device that acts in one or more ways to deliver a voltage of the proper level and characteristics to enable load equipment to function properly. In some uses, power conditioner refers to a voltage regulator with at least one other function to improve power quality (e.g. power factor correction, noise suppression, transient impulse protection, etc.)条件器 specifically work to smooth the sinusoidal A.C wave form and maintain a constant voltage over varying loads.

Neutral-line current
As the neutral point of an electrical supply system is often connected to earth ground, ground and neutral are closely related. Neutral is a circuit conductor that carries current in normal operation, which is connected to ground (or earth).Current carried on a grounding conductor can result in objectionable or dangerous voltages appearing on equipment enclosures, so the installation of grounding conductors and neutral conductors is carefully defined in electrical regulations. Where a neutral conductor is used also to connect equipment enclosures to earth, care must be taken that the neutral conductor never rises to a high voltage with respect to local ground.
The task of a power converter is to process and control the flow of electric energy by supplying voltages and currents in a form that is optimally suited for the user loads. Energy was initially converted in electromechanical converters. Today, with the development and the mass production of power semiconductors; static power converters find applications in numerous domains and especially in particle accelerators. They are smaller and lighter and their static and dynamic performances are better.

A static converter is a meshed network of electrical components that acts as a linking, adapting or transforming stage between two sources, generally between a generator and a load.

**PROPOSED SYSTEM**

**II. THREE-PHASE FOUR-WIRE HYBRID POWER FILTER**

The zig-zag transformer, connected to the load in parallel, has been employed to attenuate the neutral-line current [1], [3], [4]. However, the attenuation of neutral-line current is dependent on the ratio between the impedance of the utility system and the zig-zag transformer. Furthermore, the zig-zag transformer also has a low impedance path for zero-sequence voltage of the unbalanced utility, which will further cause a significant neutral-line current [4]. A single-phase power converter can be combined with the zig-zag transformer to advance the performance of the neutral-line current suppression [5], [6]. The single-phase power converter is inserted at the neutral line between the load and the utility, thus causing fluctuation in the ground voltage of the load. A neutral-current suppression scheme, configured by a Y transformer and a single-phase power converter connected in series, is connected to the load in parallel to suppress the neutral-line current [7]. The neutral line of the load is directly connected to that of the utility, and the fluctuation in ground voltage of the load can thus be avoided. A series of active power filters connected to the neutral line between the utility and the load can suppress the neutral-line current, thus eliminating the need of the transformer for a zero current path [8]. However, there is fluctuation in ground voltage of the load because the neutral lines of the load and utility are separated.

A new hybrid power conditioner for solving the problems of harmonic currents and neutral-line current in three-phase four-wire distribution power systems is proposed in this paper. This hybrid power conditioner is configured by a neutral-line current attenuator and a hybrid power filter. The hybrid power filter, configured by a three-phase power converter and a three-phase tuned power filter, is utilized to filter the nonzero-sequence harmonic currents in the three-phase four-wire distribution power system. The neutral-line current suppressor is connected between the power capacitors of the three-phase tuned power filter and the neutral line to attenuate the neutral-line current in the three-phase four-wire distribution power system. The proposed hybrid power conditioner can effectively reduce the power rating of passive and active elements.

**CONTROL STRATEGY**

![Fig. 3. Control block diagram of the three-phase and single-phase power converters.](image-url)
Fig. 3 shows the control block diagram of three-phase and single-phase power converters. The three-phase power converter adopts the current-mode control. The current references should be calculated first. The current references should be equal to (1)–(3), and they contain a fundamental signal and a harmonic signal. The detected three-phase utility currents are sent to the bandstop filters to extract their harmonic components.

The outputs of the bandstop filters are sent to the amplifier with gain , and the harmonic signals of the current references are then obtained. The detected dc bus voltage of the three-phase power converter is compared with the setting voltage, and the compared result is sent to a proportional-integral (PI) controller. The output of the PI controller is.

Both the outputs of the PI controller and the detected three-phase utility voltages are sent to the multipliers so that the fundamental signals of the current references are obtained. The current references are obtained by summing up the harmonic signals and the fundamental signals. The detected output currents of the three-phase power converter are compared with the current references, and the compared results are then sent to the controllers. The outputs of the controllers are sent to the PWM circuits to generate the driver signals of the power-electronic switches for the three-phase power converter.

The feed forward control is employed to control the single-phase power converter. The neutral-line current of the utility can be obtained by summing up the detected three-phase utility currents and is then sent to an amplifier of gain . The output of the amplifier is sent to the PWM circuit to serve as the modulation signal. The PWM circuit adopts unipolar PWM to generate four PWM signals for the power-electronic switches of the single-phase power converter.

V. CONCLUSION
A new hybrid power conditioner for solving the problems of harmonic currents and neutral-line current in three-phase four wire distribution power systems is proposed in this paper. This hybrid power conditioner is configured by a neutral-line current attenuator and a hybrid power filter. The hybrid power filter, configured by a three-phase power converter and a three phase tuned power filter, is utilized to filter the nonzero-sequence harmonic currents in the three-phase four-wire distribution power system.
