ABSTRACT

Segmentation of text from badly degraded document image is a very challenging task due to the high inter/intravariation between the document background and the foreground text of different document images. In this paper, we propose a novel document image binarization technique that addresses these issues by using adaptive image contrast. The adaptive image contrast is a combination of the local image contrast and the local image gradient that is tolerant to text and background variation caused by different types of document degradations. In the proposed technique, an adaptive contrast map is first constructed for an input degraded document image. The contrast map is then binarized and combined with Canny's edge map to identify the text stroke edge pixels.

The document text is further segmented by a local threshold that is estimated based on the intensities of detected text stroke edge pixels within a local window. The proposed method is simple, robust, and involves minimum parameter tuning. It has been tested on three public datasets that are used in the recent document image binarization contest (DIBCO) 2009 & 2011 and handwritten-DIBCO 2010 and achieves accuracies of 93.5%, 87.8%, and 92.03%. respectively, that are significantly higher than or close to that of the best- performing methods reported

in the three contests. Experiments on the Bickley diary dataset that consists of several challenging bad quality document images also show the superior performance of our proposed method, compared with other techniques

INTRODUCTION

DOCUMENT Image Binarization is performed in the preprocessing stage for document analysis and it aims to segment the foreground text from the document background. A fast and accurate document image binarization technique is important for the ensuing document image processing tasks such as optical character recognition (OCR). Though document image binarization has been studied for many years, the thresholding of degraded document images is still an unsolved problem due to the high inter/intra- text strokeand thedocumentbackground across different document images. As illustrated in Fig. 1, the handwritten text within the degraded documents often shows a certain amount of variation in terms of the stroke width, stroke brightness, stroke connection, and document background. In addition, historical documentsare often degradedby the bleed- through as illustrated in Fig. 1(a) and (c) where the ink of the other side seeps through to the front. In addition, historical documents are often degraded by different types of imaging artifacts as illustrated in Fig. 1(c)

LITERATURE SURVEY

Many thresholding techniques have been reported for document image binarization. As many degraded documents do not have a clear bimodal pattern, global thresholding is usually not a suitable approach for the degraded document binarization. Adaptive thresholding, which estimates a local threshold for each document image pixel, is often a better approach to deal with different variations within degraded document images. For example, the early windowbased adaptive thresholding techniques estimate the local threshold by using the mean and the standard variation of image pixels within a local neighborhood window. The main drawback of these window-based thresholding techniques is that the thresholding performance depends heavily on the window size and hence the character stroke width. Other approaches have also been reported, including background subtraction, texture analysis, recursive method, decomposition method, contour completion, Markov Random Field, matched wavelet, cross section sequence graph analysis, self-learning, Laplacian energy user assistance and combination of binarization techniques. These methods combine different types of image information and domain knowledge and are often complex. The local image contrast and the local gradient are very useful features image for segmenting the text from the document background because the document text usually has certain image contrast to the neighboringdocument background. They veryeffectiveand are have beenused in manydocumentimage binarization techniques. In Bernsen'spaper, the local contrast is defined as follows:

C(i, j)=Imax(i, j)-Imin(i, j) (1)

where C(i, j) denotes the contrast of an image pixel (i, j), Imax(i, j) and Imin(i, j) denote the maximum and minimum intensities within a local neighborhood windows of (i, j), respectively. If the local contrast C(i, j) is smaller than a threshold, the pixel is set as background directly. Otherwise it will be classified into text or background by comparing with the mean of Imax(i, j) and Imin(i, j). Bernsen's method is simple, but cannot work properly on degraded document images with a complex document background. We have earlier proposed a novel document image binarization method by using the local image contrast that is evaluated as follows:

C(i, j) = Imax(i, j) - Imin(i, j) Imax(i, j) + Imin(i, j) + (2)

where is a positive but infinitely small number that is added in case the local maximum is equal to 0.

A Peer Reviewed Open Access International Journal

Compared with Bernsen's contrast in Equation 1, the local image contrast in Equation2 introduces normalization factor (the denominator) to compensate the image variation within the document background. Take the text within shaded document areas such as that in the sample document image in Fig. 1(b) as an example. The small image contrast around the text stroke edges in Equation 1 (resulting from the shading) will be compensated by a small normalization factor (due to the dark document background) as defined in Equation 2.

PROPOSED METHOD:

This section describes the proposed document image binarization techniques. Given a degraded document image, an adaptive contrast map is first constructed and the text stroke edges are then detected through the combination of the binarized adaptive contrast map and the canny edge map. The text is then segmented based on the local threshold that is estimated from the detected text stroke edge pixels. Some post-processing is further applied to improve the document binarization quality.

Contrast Image Construction:

The image gradient has been widely used for edge detection and it can be used to detect the text stroke edges of the document images effectively that have a uniformdocument background. On the other hand, it often detects many non- stroke edgesfrom the background of degraded document that often contains certain image variationsdue to noise, uneven lighting, bleed-through, etc. Toextract only the stroke edges properly, the image gradient needs to be normalized to compensate the image variation within the document background. In our earlier method, The local contrast evaluated by the local image maximum and minimum is used to suppress the background variation as described in Equation 2. In particular, the numerator (i.e. the difference between the local maximum and the local minimum) captures the local image difference that is similar to the traditional image gradient

The denominator is a normalization factor that suppresses the image variation within the document background. For image pixels within bright regions, it will produce a large normalization factor to neutralize the numerator and accordingly result in a relatively low image contrast. For the image pixels within dark regions, it will produce a small denominator and accordingly result in a relatively high image contrast. However, the image contrast in Equation 2 has one typical limitation that it may not handle document images with the bright text properly. This is because a weak contrast will be calculated for stroke edges of the bright text where the denominator in Equation 2 will be large but the numerator will be small. To overcome this over-normalization problem, we combine the local image contrast with the local image gradient and derive an adaptive local image contrast as follows:

 $Ca(i, j)=\alpha C(i, j)+(1-\alpha)(Imax(i, j)-Imin(i, j)) (3)$

A Peer Reviewed Open Access International Journal

where C(i, j) denotes the local contrast in Equation 2 and (Imax(i, j) - Imin(i, j)) refers to the local image gradient that is normalized to. The local windows size is set to 3 empirically. α is the weight between local contrast and local gradient that is controlled based on the document image statistical information. Ideally, the image contrast will be assigned with a high weight (i.e. large α) when the document image has significant intensity variation. So that the proposed binarization technique depends more on the local image contrast that can capture the intensity variation well and hence produce good results. Otherwise, the local image gradient will be assigned with a high weight. The proposed binarizationtechniquerelies more on image gradient and avoid the over normalization problem of our previous method. We model the mapping from document image intensity variation to α by a power function as follows: α =Std 128 γ . (4) where Std denotes the document image intensity standard deviation, and γ is a pre-defined parameter. The power function has a nice property in that it monotonically and smoothly increases from 0 to 1 and its shape can be easily controlled by different γ . γ can be selected from $[0,\infty]$, where the power function becomes a linear function when $\gamma = 1$. Therefore, the local image gradient will play the major role in Equation 3 when γ is large and the local image contrast will play the major role when γ is small. The setting of parameter γ will be discussed in Section IV. Fig. 2 shows the contrast map of the sample document images in Fig. 1 (b) and (d) that are created by using local image gradient, local image contrast and our proposed method in Equation 3, respectively. For the sample document with a complex document back- ground in Fig. 1(b), the use of the local image contrast produces a better result as shown in Fig. 2(b) compared with the result by the local image gradient as shown in Fig. 2(a) (because the normalization factors in Equation 2 helps to suppress the noise at the upper left area of Fig. 2(a)). But for the sample document in Fig. 1(c) that has small intensity variation within the document background but large intensityvariation within the text strokes, the use of the local image contrast removes many light text strokes improperly in the contrast map as shown in

Fig. 2(b) whereas the use of local image gradient is capable of preserving those light text strokes as shown in Fig. 2(a). As a comparison, the adaptive combination of the local image contrast and the local image gradient in Equation 3 can produce proper contrast maps for document images with different types of degradation as shown in Fig. 2(c). In particular, the local image contrast in Equation 3 gets a high weight for the document image in Fig. 1(a) with high intensity variation within the document background whereas the local image gradient gets a high weight for the document image in Fig. 1(b).

Text Stroke Edge Pixel Detection:

The purpose of the contrast image construction is to detect the stroke edge pixels of the document text properly. The constructed contrast image has a clear bi-modal pattern, where the adaptive image contrast computed at text stroke edges is obviously larger than that computed within the document background .We thereforedetect the text stroke edge pixel candidate by using Otsu's global thresholding method. For the contrast images in Fig. 2(c), Fig. 3(a) shows a binary map by Otsu's algorithm that extracts the stroke edge pixels properly. As the local image contrast and the local image gradient are evaluated by the difference between the maximum and mini- mum intensity in a local window, the pixels at both sides of the text stroke will be selected as the high contrast pixels. The binary map can be further improved through the combination with the edges by Canny's edge detector, because Canny's edge detector has a good localization property that it can mark the edges close to real edge locations in the detecting image. In addition, canny edge detector uses two adaptive thresholds and is more tolerant to different imaging artifacts such as. Algorithm 1:Edge Width Estimation Require: The Input Document Image I and Corresponding Binary Text Stroke Edge Image Edg. Ensure: The Estimated Text Stroke Edge Width EW 1. Get the width and height of I 2. for Each Row i = 1 toheight in Edg do 3. Scan from left to right to find edge pixels that meet the following criteria: a) its label is 0 (background); b) the next pixel is labeled as 1(edge). 4. Examine the

A Peer Reviewed Open Access International Journal

intensities in I of those pixels selected in Step 3, and remove those pixels that have a lower intensity than the following pixel next to it in the same row of I. 5. Match the remaining adjacent pixels in the same row into pairs, and calculate the distance between the two pixels in pair. 6. end for 7. Construct a histogram of those calculated distances. 8. Use the most frequently occurringdistance as the estimated stroke edge width EW.

Local threshold optimization:

The text can then be extracted from the document back- ground pixels once the high contrast stroke edge pixels are detected properly. Two characteristics can be observed from different kinds of document images: First, the text pixels are close to the detected text stroke edge pixels. Second, there is a distinct intensity difference between the high contrast stroke edge pixels and the surrounding background pixels. The document image text can thus be extracted based on the detected stroke edge pixels as follows: text The neighborhoodwindow should be at least larger than the stroke width in order to contain stroke edge pixels. So the size of the neighborhoodwindow W can be set based on the stroke width of the document image under study, EW, which can be estimated from the detected stroke edges [shown in Fig. 3(b)] as stated in Algorithm 1. Since we do not need a precise stroke width, we just calculate the most frequently distance between two adjacent edge pixels (which denotes two sides edge of a stroke) in horizontal direction and use it as the estimated stroke width. First the edge image is scanned horizontally row by row and the edge pixel candidates are selected as described in step 3.

Post processing:

Once the initial binarization result is derived from Equation 5 as described in previous subsections, the binarization. Algorithm 2:Post-Processing Procedure Require: The Input Document Image I, Initial Binary Result B and Corresponding Binary Text Stroke Edge Image Edg Ensure: The Final Binary Result 1. Find out all the connect components of the stroke edge pixels in Edg. 2. Remove those pixels that do not connect with other pixels. 3. for Each remaining edge pixels (i, j): do 4. Get its neighborhood pairs: (i - 1, j)and (i + 1, j); (i, j - 1) and (i, j + 1) 5. if The pixels in the same pairs belong to the same class (both text or background) then 6. Assign the pixel with lower intensity to foreground class (text), and the other to background class. 7. end if 8. end for 9. Remove single-pixel artifacts along the text stroke boundaries after the document thresholding. 10. Store the new binary result. Result can be further improvedby incorporatingcertain domain knowledge as described in Algorithm 2. First, the isolated foreground pixels that do not connect with other foreground pixels are filtered out to make the edge pixel set precisely. Second, the neighborhood pixel pair that lies on symmetric sides of a text stroke edge pixel should belong to different classes (i.e., either the document background the foreground text). One pixel of the pixel pair is therefore labeled to the other category if both of the two pixels belong to the same class. Finally, some single-pixel artifacts along the text stroke boundaries are filtered out by using several logical operators as described in IV.

DISCUSSION:

As described in previous sections, the proposed method involves several parameters, most of which can be automatically estimated based on the statistics of the input document image. This makes our proposed stable technique more and easy-to-usefor documentimages with different kinds of degradation. The superior performance of our proposed method can be explained by several factors. First, the proposed method combines the local image contrast and the local image gradient that help to suppress the background variation and avoid the over-normalization of document images with less variation. Second, the combination with edge map helps to produce a precise text stroke edge map. Third, the proposed method makes use of the text stroke edges that help to extract the foregroundtext from the documentbackgroundaccurately.But the performance on Bickley diary dataset and some images of DIBCO

A Peer Reviewed Open Access International Journal

contests still needs to be improved, we will explore it in future.

CONCLUSION:

This paper presents an adaptive image contrast based document image binarization technique that is tolerant to different types of document degradation such as uneven illumination and document smear. The proposed technique is simple and robust, only few parameters are involved. Moreover, it works for different kinds of degraded document images. The proposed technique makes use of the local image contrast that is evaluated based on the local maximum and minimum. The proposed method has been tested on the various datasets. Experiments show that the proposed method outperforms most reported document binarization methods in term of the Fmeasure, pseudo F-measure, PSNR, NRM, MPM and DRD.
